

- a. `const` storageID = ``kc-house-price-multi``;  
Update the heatmaps
1. Change the final part of `plotPredictionHeatmap` to split or "unstack" the tensor, one for each label, and display each as a heatmap:

- a. `tf.unstack(values, 2).forEach((values, i) => {`
- b. `const data = {`
- c. `values,`
- d. `xTickLabels,`
- e. `yTickLabels,`
- f. `});`
- g.
- h. `tfvis.render.heatmap({`
- i. `name: `Bedrooms: ${getClassName(i)} (local)`,`
- j. `tab: "Predictions"`
- k. `}, data, {height: size});`
- l. `tfvis.render.heatmap({`
- m. `name: `Bedrooms: ${getClassName(i)} (full`
- n. `domain)`,`
- o. `tab: "Predictions"`
- p. `}, data, {height: size, domain: [0, 1]});`

## Making predictions

1. Update the predict function to handle multiple outputs:

```
a. const outputs = outputTensor.dataSync();
b. let outputString = "";
c. for (let i = 0; i < 3; i++) {
d.   outputString += `Likelihood of having
   ${getClassName(i)} bedrooms is:
   ${((100*outputs[i]).toFixed(1))}%<br>`;
e. }
f. document.getElementById("prediction-
   output").innerHTML = outputString;
```
